My goal is to create a method that will match students who have questions regarding certain careers and match them with professionals, in those specific fields, who can answer them.

I am going to build a recommendation engine that uses collaborative filtering/matrix factorization to recommend student questions to professionals (based on content similarity, professional background, etc.)

A company that has an online form for students to receive timely feedback on career related questions by professionals in that field. Currently they are having problems with pairing students with reliable career services. The U.S. has almost 500 students for every guidance counselor. Underserved youth lack the network to find their career role models, making CareerVillage.org the only option for millions of young people in America and around the globe with nowhere else to turn. My background and passion has been in career coaching so this topic relates to my interests and along with some previous job experience.

Some features in my dataset include multiple tables, the questions and what industry they were tagged with, the different kinds of professionals along with which field they are from, and the emails of the student and the professional. Since I am building a recommendation system to match these two populations, I believe the data collected will be able to answer

If successful, this model can incorporate into the site enabling better recommendations for professionals (volunteers). This inturn reduces the time required from the volunteer and enables them to answer a greater quantity of questions.

I expect to go deeper into Spark to build a recommendation system, leverage AWS to house all of my relational databases, and focus on using unsupervised methods to cluster the data into different groups for use in the modeling.
